## HEALTH TECHNOLOGY ASSESSMENT ENDOBRONCHIAL ULTRASOUND (EBUS)

### 1. INTRODUCTION

#### 1.1 Lung cancer

males (13.8% of cancer in males) and the 8<sup>th</sup> commonest among the females (3.8%). The Age-standardized incidence rate (ASR) was 20.3 for males and 6.5 for females.

(7.8%).

(SCLC) or non-small cell type lung cancer (NSCLC), and the presence of mediastinal involvement or distant spread of the tumour. The treatment of SCLC is mainly chemotherapy whereas NSCLC treatment is fully stage dependent ranging from

experimental chemotherapy / radiotherapy. Non-small cell lung cancer (NSCLC) usually metastasizes first to hilar and mediastinal lymph nodes. Subsequently,

For staging of the NSCLC, the TNM classification has been developed in which T stands for local tumour extension, N for lymph node metastasis and M for distant

for the description of the N factor of the TNM classification. The TNM classification is subdivided in cTNM and a pTNM where the cTNM while the pTNM is based on the pathological results of the operation. lymph node enlargement occurs in up to 38% of NSCLC at diagnosis. Mediastinal lymph node staging can be divided into imaging and sampling. Computed Tomography (CT), magnetic resonance imaging (MRI), and positron emission tomography (PET)

lesions can be performed by mediastinoscopy, thoracoscopy, transthoracic fine- with fine needle aspiration.

#### 1.2 Endobronchial ultrasound (EBUS)

Transbronchial needle aspiration (TBNA) of mediastinal lesions, has been reported since 1940's and can be performed during routine bronchoscopy. Currently, "blind" TBNA is only performed by 27% of chest physician because of the lack of real time monitoring of the needle. The yield of TBNA can be increased, especially for those nodes outside the subcarinal region, by using endobronchial ultrasound (EBUS) to locate the node prior to TBNA.

under local anaesthesia. Limitation of this radial EBUS "localisation method" is that

real-time ultrasound control from the trachea bronchial tree. With EBUS-TBNA the para-tracheal (stations 2 and 4), subcarinal (station 7) hilar and intrapulmonary nodes (stations 10 and 11) can be reached.

EBUS guided transbronchial aspiration (EBUS-TBNA) improved the results of N-staging of lung cancer, especially in difficult lymph node levels without any clear endoscopic landmarks. The possibility of identifying N2 and N3 stages by means of a

approach under fluoroscopic or CT guidance is the standard procedure. However, instead of fluoroscopic guidance and also plays an important role in the strategy for

### 1.3 Competing diagnostic technologies

Neither CT scan nor MRI are able to distinguish malignant from hyper plastic, granulomatous or fibrotic lesions. With reported sensitivities and specificities of 69% and 71% for CT scan and 45% and 65% for MRI, both techniques prove too

fluoro-2-deoxyflucose (FDG) and CT scan showed that PET was significantly more accurate than CT scan in demonstrating nodal metastasis.

stations (level 2R, 2L, 4R and 4L) and the anterior subcarinal lymph node station (level 7), access to the posterior and inferior mediastinum is limited and requires either

Endoscopic ultrasound with fine needle aspiration (EUS-FNA) offers a minimally

limitation of EUS-FNA is its inability to visualise stations anterior and superior to the

made by the Consultant Respiratory, who is also the Director of the Respiratory Medical Institute (IPR). It is intended for the use of health planners and policy makers.

### 5.3 Data extraction

All the relevant articles were retrieved and appraised by two reviewers using Critical Appraisal Skills Programme (CASP) depending on the type of study design.

5) and was discussed with the expert committee before deciding on the eligibility

commentaries were excluded. All articles were classified according to the levels of evidence for assessing diagnosis using Oxford Centre for Evidence-based Medicine Levels of Evidence (May 2001). (Appendix 1)

## 6. RESULTS AND DISCUSSION

to be presented in the evidence tables for accuracy/effectiveness/ safety of EBUS in

### 6.1 Diagnostic accuracy / effectiveness

The accuracy / effectiveness of EBUS in diagnosis and therapeutic strategies of central tumour, in diagnosis of mediastinal / hilar lymph nodes and staging of lung

#### 6.1.1 EBUS in the Diagnostic and Therapeutic Strategies of Central Cancer

A total of five articles related to centrally located lung cancer and tumour invasion of the bronchial wall were identified. Determination of the depth of invasion of

most important finding for determining the appropriate mode of therapy, whether

Kurimoto et al. described the correspondence between the microscopic findings of

wall in extrapulmonary and intrapulmonary bronchi was described as a five-

invasion between EBUS findings and histological findings in 23 out of 24 (95.8%)

(EBUS) images and histologic findings in normal and tumour-invaded bronchial

The layers were confirmed by microscopic findings. EBUS images of the bronchi. However, there was an additional findings: a membranous portion lacking

1.90 mm) and the actual histological measurement 1.03 mm (range, 0.62-1.75)

Comparison of the echo intensity of the ultrasonogram of the bronchus produced

(NIH Image) was described by Nakamura et al. echo intensity curves showed five peaks and troughs, indicating that the normal bronchial wall is a laminar structure consisting of five ultrasonically different

and fourth layer were significantly greater with the 30-MHz probe than the 20-

of the normal five layers and the tumour has invaded beyond the bronchial wall.

et al. studied the ability of EBUS to differentiate between airway infiltration within the chest who underwent surgery following chest CT and bronchoscopic

present in 49 patients (47%) and tumour impression in 56 patients (53%). The pathologic examination after surgery showed tumour invasion in 55 patients (52%) and tumour impression in 50 patients (48%). Examination of the tracheobronchial tree with EBUS for possible infiltration by a central tumour yielded an accuracy

of 94%, a sensitivity of 89%, and a specificity of 100% which is higher than chest CT. Chest CT scanning yielded an accuracy of 51%, a sensitivity of 75%, and a specificity of 28%. The correlation between EBUS classification and the postoperative classification of airway involvement was highly significant (correlation 0.89,  $p < 0.01$ ).

therapy (PDT) among patients with centrally located lung cancer.

and HR-CT. According to evaluation by EBUS, 9 of these 18 lesions including three CIS were diagnosed as intracartilaginous, because the cartilage was not

as determined by bronchoscopy, five lesions protruded beyond the cartilage when image by EBUS and was later confirmed histopathologically.

depth of the tumour invasion estimated by HR-CT indicated that 11 lesions

were invisible on HR-CT, invaded beyond the cartilage as shown by EBUS. EBUS

than did bronchoscopy or HR-CT.

the histopathologic findings were identical in the six patients. None of these patients has developed a recurrence. Median follow-up:  $22.3 \pm 13.8$  months.

bronchoscopy and HR-CT to improve the efficacy of PDT in patients with centrally

### **6.1.2 EBUS of mediastinal / hilar lymph nodes in the Diagnosis and Staging of Lung Cancer**

One of the primary goals of EBUS was the detection and the TBNA of mediastinal

of 16 articles were identified. There were three Randomized Control Trials, 11

Herth et al. published his earlier experience using EBUS-TBNA in 242 patients (86%) the lymph nodes were successfully accessed by TBNA (specific diagnosis or lymphocytes on specimen) and was able to establish diagnosis or a definitive staging in 172 patients out of 242 patients (71%).

EBUS and EBUS plus CT were more accurate than CT alone in imaging of the

EBUS for hilar lymph nodes was twice of CT scan (54% and 27% respectively). However, positive rate of EBUS and CT scan was the same 27%. The detection rates for mediastinal lymph nodes by EBUS and Chest CT scan were 86% and

ability of EBUS was superior to that of CT scan in identifying lymph nodes < 10 mm in diameter. Detection accuracy of lymph node metastasis by Chest CT scan and EBUS in 16 surgical cases showed that the sensitivity and specificity of EBUS alone was 67% and 92% respectively. The sensitivity and specificity of chest CT was 75% and 83% respectively. Combination of EBUS plus chest CT yielded a sensitivity of 100% and a specificity of 77%. Overall accuracy of EBUS

Herth et al. and Munavvar et al. investigated the results of EBUS guided TBNA as compared to conventional TBNA.

enlarged lymph nodes referred for TBNA were randomized into two groups: 100 patients underwent EBUS guided TBNA and 100 patients underwent conventional TBNA.

subcarinal lymph nodes were randomized and analyzed separately (group A)

were randomized into group B by computer. The yield of TBNA in group A for conventional TBNA was 74% compared to 86% in the EBUS-guided group. The difference was statistically non significant ( $p=0.3$ ). In the group B, the overall yield of conventional TBNA was 58% compared to 84% in the EBUS-guided TBNA. The difference was statistically significant ( $p<0.001$ ). The combined yield for groups A and B was 71% for conventional TBNA versus 80% for EBUS guidance ( $p < 0.05$ ).

in diagnostic yield from 46.2% with conventional TBNA to 88.9% with EBUS guided TBNA.

Diagnostic rate of EBUS guided TBNA was shown to be significantly higher

bronchoscope as shown by Kanoh et al. Fifty-five patients with mediastinal and / or hilar lymphadenopathy were randomized into EBUS-D and EBUS-S group. Diagnostic rate of EBUS-D was significantly higher than EBUS-S (97% versus 76%,  $p=0.025$ ).

needle aspiration of mediastinal and hilar lymph nodes using convex probe (CP) EBUS were demonstrated by Herth et al., Yasufuku et al. and Krasnik et al. Herth et al. in a study involving 502 patients referred for TBNA for diagnosis of

diagnostic yield of 535 out of 572 nodes (93.5%) was reported. Analysing the diagnostic yield for 502 patients, a definitive diagnosis was established in 470 patients (93%). The sensitivity was 94%, specificity 100%, accuracy 94%, PPV 100% and NPV 11%. Procedure was not influenced by lymph node location and Yasufuku et al. yielded an overall sensitivity, specificity and diagnostic accuracy rate of direct CP-EBUS guided TBNA in distinguishing benign and

lesions, the aspirated materials obtained was diagnostic in all cases. EBUS-FNA identified malignant cells in 13 lesions and benign cells in two.

Plat et al. demonstrated that EBUS-TBNA allowed diagnosis to be reached in 27 out of 33 (82%) of patients with Positron Emission Tomography with 18-fluorodeoxyglucose (FDG-PET) positive mediastinal lesions referred for staging and / or diagnosis. Seventy eight percent (21/27) were diagnosed after previous EBUS localization. Previous localization with EBUS was associated with a TBNA

sampling of mediastinal lymph nodes) was avoided by the positive results of TBNA in 25 cases (76%) of patients. Nakajima et al. described the ability of EBUS-TBNA in diagnosing pre tracheal lymph node metastases from renal

Comparison of Endobronchial ultrasound guided transbronchial biopsy (EBUS-TBNA) and Transesophageal fine needle aspiration (EUS-FNA) was evaluated by

lymph nodes (1cm) as assessed by contrast-enhanced computed tomography

in positions 5,6, or 11 (which are accessible only by bronchoscopy) and stations 8 and 9 (which are accessible only by esophagoscopy). Patients were

on their image findings. Patients underwent ultrasound-guided transbronchial (EBUS-TBNA) and transesophageal needle biopsies (EUS-FNA) in a cross over design. Transbronchial approach was successful in 142 patients (88%), and was

diagnostic in 76%. For each station, the number of positive samples (successful) for the transbronchial / transesophageal approaches was: 2R: 19/13; 2L: 16/19; 3: 17/15; 4R: 19/12; 4L: 17/20; 7:19/20; 10R: 18/9; and 10L: 17/18. Combining the

nodes was achieved in 97% of patients and resulted in a specific diagnosis in

were neither clinically nor statistically significant. Combining both approaches is

EBUS-TBNA has been used to stage 256 patients in published papers.  
Correct prediction of lung cancer staging was assessed by Yasufuku

suspected of malignancy detected on CT were included in the study. In 105 patients, EBUS-TBNA was successfully performed to obtain samples from 163

(2.8%). The diagnostic value of EBUS-TBNA in correct prediction of lymph node

specificity of 100%, positive predictive value (PPV) of 100%, negative predictive value (NPV) of 89.5%, and diagnostic accuracy rate of 96.3%. As a result, 29 mediastinoscopies, 8 thoracotomies, 4 thoracoscopies, and 9 CT-guided PCNB were avoided by EBUS-TBNA.

EBUS-TBNA has a high sensitivity as well as specificity compared to CT or PET  
Yasufuku et al. in a

suspected lung cancer, demonstrated that the sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy of EBUS-TBNA in the correct prediction of mediastinal lymph nodes staging were 92.3%, 100%, 100%, 97.4%, and 98.0% respectively. The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy of CT in the prediction of mediastinal lymph node staging were 76.9%, 55.3%, 37.0%, 87.5% and 60.8% respectively. The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy of PET in

91.5% and 72.5% respectively. There is a significant difference in the accuracy of the three different modalities ( $p < 0.00001$ ). Similarly, EBUS-TBNA had 100% sensitivity, specificity and PPV compared to PET/CT which had sensitivity of 67%, specificity of 68%, PPV of 40% and NPV of 87% as shown by Krasnik

endobronchial ultrasound real-time fine needle aspiration for staging of

20 patients with known or suspected lung cancer, EBUS-TBNA was performed together with additional EUS examination in whom the staging CT scan had

inferiorly placed lymph nodes in station 7). EBUS-TBNA was undertaken in 18 out of 20 patients and additional EUS-FNA in six out of seven patients. From 18 patients undergoing EBUS-TBNA ±EUS-FNA, 11 patients resulted in

false negative. For the 18 patients who underwent EBUS-TBNA the sensitivity, specificity and accuracy were 85% (95% CI- 54.6-98.1), 100% (95% CI-47.8-

100) and 89% (95% CI -65.3-98.6) respectively. Additional findings attributable to the EUS-FNA were noted in every case. EBUS-TBNA can be used to identify

to the posterior –inferior lymph node stations 5, 7, 8 and 9.

### 6.1.3 EBUS in Peripheral Pulmonary Lesions

Twelve studies, including three Randomized Control Trials were identified and

by Kurimoto et al. and Chao et al.

were identified by EBUS based on the internal structure of the lesion.

patent vessels and patent bronchioles; type 1b, without vessels and bronchioles); type 11, hyperechoic dots and linear arcs pattern type(11a, without vessels; type 11b, with patent vessels); and type 111, heterogenous pattern (type 111a, with hyperechoic dots and short lines; type 111b, without hyperechoic dots and short lines). Twenty-three of 25 type 1 lesions (92.0%) were benign, while 98 of 99 type 11 and 111 lesions (99.0%) were malignant. Twenty- one of 24 type 11 lesions (87.5%) were well-differentiated adenocarcinomas, and all type 111b lesions were malignant, including 18 poorly differentiated adenocarcinomas (81.8%).

In another study, Chao et al. described four image patterns: (1) continuous hyperechoic margin outside the lesion, (2) homogenous or heterogenous internal echoes, (3) hyperechoic dots in the lesion, and (4) concentric circles along the echo probe. Comparisons of EBUS image patterns to clinical diagnosis in 93

0.030) respectively. Images with homogenous internal echoes were more likely to be non neoplasm lesions by univariate analysis ( $p<0.001$ ) but the significance of internal echoes was lost after multivariate analysis (0.674). Approximately

Usually the procedure is performed as a transbronchial biopsy with fluoroscopy

patients referred for transbronchial biopsy (TBBX) for peripheral lesions underwent fluoroscopy-guided and EBUS-guided TBBX in random order. In EBUS-guided TBBX diagnosis was established in 40 patients (80%). Under fluoroscopic guidance, diagnosis was established in 38 patients (76%). There is a non significant trend for EBUS to be better than fluoroscopy for lesions < 3 cm in diameter (80% versus 57%). In nine patients (18%), the diagnosis obtained by bronchoscopy saved a surgical procedure (sarcoidosis (2), tuberculosis (2), infection (1), metastatic disease (1), and small cell lung cancer (3).

assigned to EBUS-TBB or TBB only. A definitive diagnosis was obtained by EBUS-TBB in 66 of 87 patients (75.8%) and by conventional TBB in 62 of 119 patients (52.1%). Analysis of patients with malignant disease in the EBUS-significantly higher than TBB ( $p=0.004$  and  $p=0.007$ , respectively). Sensitivity

of patients with  $> 3$  cm showed no significant difference in diagnostic ability

in lesions  $< 2$ cm, [23% (TBB) versus 71% (EBUS-TBB)]  $p=0.001$ .

Chung et al. in his randomized control trial involving 158 patients showed that measuring and applying the distance between the orifice of the bronchus and

biopsies (TBBs) for peripheral lesion.

two groups – EBUS-D group (EBUS TBBs with measured distance prior to biopsy) and EBUS group (without measured distance). The diagnostic yield of TBBs in group EBUS-D patients was 78.9% (45/57) which was significantly higher than in group EBUS patients 57.1% (32/56) ( $p=0.013$ ). Gender, age, size of lesions,

the two groups. Factors that influenced the diagnostic yield of EBUS-guided TBB include probe location within the lesion on EBUS image ( $p=0.001$ ) and measured distance before biopsy ( $p=0.002$ ), were statistically significant.

The ability of EBUS together with fluoroscopy to guide transbronchial lung biopsy as compared to fluoroscopy alone to guide transbronchial lung biopsy

combined EBUS and fluoroscopy guidance (Cases) and 42 patients underwent transbronchial lung biopsy under fluoroscopy guidance only (Controls). In 38 cases out of 50 cases (76%) EBUS could describe the peripheral lesion (33 from inside and 5 from adjacent bronchus). Lung cancer was diagnosed in 24 patients

cancer diagnosis and specificity for cancer exclusion were 100%, respectively (15/15, 18/18). Compared to the controls, in whom the biopsy site was determined by fluoroscopy only, the sensitivity tended to be superior by EBUS, although it did not reach statistical significance ( $p=0.06$ ). However, specificity and accuracy were statistically significant (both  $p=0.02$ ). In 25/30 cases (83.3%) with successful

The ability of endobronchial ultrasound (EBUS) using guide sheath (EBUS-GS)

lesions defined as a mass ( $>30$  mm; 24 of 26 lesions, 92%) was significantly higher than that for lesions defined as nodules  $\leq 30$ mm; 92 of 124 lesions, 74%)  $p=0.04$ . When the lesion was  $\leq 30$ mm, size does not affect the yield by EBUS-GS. The yield for lesions  $\leq 10$  mm did not decrease (76%). EBUS-GS is particularly useful for lesions  $\leq 20$  mm that are undetectable by fluoroscopy.

that diagnostic sensitivities were 44.4% (8 of 18) for lesions  $< 20$  mm in mean diameter and 91.7% (11 of 12) for lesions 20 to 30 mm in diameter.

EBUS-guided TBBX has been shown to be effective in localising and diagnosing fluoroscopically invisible pulmonary nodules as shown by a study conducted

pulmonary nodules which could not be visualized by fluoroscopy who were

with EBUS-guided TBBX (89%). The lesion could not be visualized in six patients,

left upper lobe. A diagnosis was established in 38 of these patients (70%). The diagnosis obtained by EBUS-guided TBBX averted the need for more surgery in

6).

Similarly, the diagnostic efficacy of EBUS-guided transbronchial biopsy, in the absence of fluoroscopic guidance, was evaluated in a series of consecutive

of 50 patients (74%) and histologic diagnosis could be established in 31 of these 37 (84%), cytology diagnosis in one and no diagnosis in 5 patients. For EBUS invisible lesion ( $n=13$ ), no diagnosis was obtained in 11 and cytology diagnosis was obtained in 2. In 34 patients (68%), a pathologic (histology+cytology) diagnosis

decreased to 18% whereas for lesions  $\geq 20$  mm diagnostic pathologic yield was 32/39 (82%).

Yoshikawa et al. evaluated the diagnostic value of EBUS with a guide sheath for peripheral pulmonary lesions without X-Ray fluoroscopy.

fluoroscopy and 86.2% for all bronchoscopic procedures. The diagnostic yield for PPLs  $> 20$  mm in diameter (75.6%) was significantly higher than that for lesions  $\leq 20$  mm (29.7%)  $p<0.01$ . When the bronchus leading to the PPL was identified on the CT scan, the yield was 79.2%. Solid lesions had a higher diagnostic yield (67.0%) compared to non solid lesions (35%;  $p < 0.05$ ). Multivariate analysis

predictors of diagnostic sensitivity by EBUS-GS guided bronchoscopy ( $p<0.05$ ).

#### 6.1.4 EBUS in Interventional Bronchoscopy

used before mechanical tumour destruction (346 cases, 29%), in airway stent placement (235 cases, 20%), before and during Neodymium: yttrium aluminium garnet (Nd:YAG) laser resection (148 cases, 13%), Argon-plasma coagulation APC (262 cases, 23%), brachytherapy (134, 11%), foreign body removal (22, 2%) and abscess drainage (27, 2%). In 43% of the cases where EBUS was used, it resulted in change of therapy or better guidance of the intervention. Changes of treatment

or APC was stopped when EBUS demonstrated close relationships with vessels. Severe bleed or fistula formation did not develop in any of the cases where EBUS

patients. Lymph node metastasis was confirmed by EBUS guided transbronchial

caused haemodynamic compromise. No other complications associated with EBUS

### 6.3 Cost effectiveness

Becker DH and Herth F estimated the fixed costs and long term investment are approximately \$80,000 to \$ 100,000 (US).  
by the supplier for Olympus Compact Endoscopic Ultrasound Centre and Ultrasonic Bronchofibervideoscope is RM 262,000.00. The price for Olympus Compact Endoscopic Ultrasound Centre, Ultrasonic Bronchofibervideoscope and Endoscopic Video Imaging System is RM 410,000.00

### 6.4 Training

The technology implies a switch from a surgeon (mediastinoscopy) to pulmonologist / endoscopist. The mean examination time for EBUS procedures ranges from three minutes to fifteen minutes.

proven benefit in many bronchoscopic procedures.

## 7. CONCLUSION

### 7.1 Diagnostic accuracy / Effectiveness

#### 7.1.1 EBUS in the Diagnostic and Therapeutic Strategies of Central Cancer

invasion than did bronchoscopy or HR-CT.

#### 7.1.2 EBUS of mediastinal / hilar lymph nodes in the Diagnosis and Staging of Lung Cancer

- i. EBUS-TBNA added little time but increased the diagnostic yield significantly compared to conventional TBNA in stations other than subcarinal nodes

node staging in lung cancer is higher with EBUS-TBNA than it is with other

- iii. EBUS-TBNA should be considered for staging mediastinal lymph nodes as
- iv. The combine approach of EUS-FNA and EBUS-TBNA may replace more

### 7.1.3 EBUS in Peripheral Pulmonary Lesions

bronchoscopic occult pulmonary masses  $\geq 20$  mm

of solitary pulmonary nodules that cannot be visualized by fluoroscopy

- v. Endobronchial ultrasonography with guide sheath–guided transbronchial biopsy (EBUS-GS guided TBB) without the use of radiographic fluoroscopy

### 7.1.4 EBUS in Interventional Bronchoscopy

### 7.1.5 EBUS in management of other lung diseases

## 7.2 Safety

## 7.3 Cost effectiveness

## 7.4 Training

## 8. RECOMMENDATION

Regional Respiratory Centres in Malaysia. However, centres utilizing this technology

1c			SnNouts††		analyses ††††
2a	) of	) of groups in RCTs	SR (with homogeneity*)	homogeneity*) of 2b	SR (with homogeneity*)
2b	quality RCT; e.g., <80% follow-up)	patients in an RCT; CDR†	good†††reference standards; CDR† after		costs or alternatives; limited review(s) of the studies; and including
2c	"Outcomes" Research; Ecological	"Outcomes" Research			
3a	) of		SR (with homogeneity*)	homogeneity*) of 3b	SR (with homogeneity*)
3b	Individual Case- Control Study		Non-consecutive study;	Non-consecutive	
4	Case-series (and )	Case-series (and )	Case-control study, poor	Case-series	
5	"first principles"	research or "first principles"	bench research or "first principles"	research or "first principles"	"first principles"

**Notes**

Users can add a minus-sign “-” to denote the level of that fails to provide a conclusive answer because of:

- EITHER a single result with a wide Confidence Interval (such that, for example, an ARR in an RCT is not statistically significant but whose confidence intervals fail to exclude clinically important benefit or harm)
- OR a Systematic Review with troublesome (and statistically significant) heterogeneity.
- Such evidence is inconclusive, and therefore can only generate Grade D recommendations.

	By homogeneity we mean a systematic review that is free of worrisome variations (heterogeneity) in the directions and degrees of results between individual studies. Not all systematic reviews with statistically significant heterogeneity need be worrisome, and not all worrisome heterogeneity need be statistically significant. As noted above, studies displaying worrisome heterogeneity should be tagged with a “-” at the
†	Clinical Decision Rule. (These are algorithms or scoring systems which lead to a prognostic estimation or a diagnostic category. )
	See note #2 for advice on how to understand, rate and use trials or other studies with wide confidence
	patients died before the Rx became available, but some now survive on it; or when some
	study we mean one that failed to clearly define comparison groups and/or failed to measure exposures and outcomes in the same (preferably blinded), objective way in both exposed and non-exposed individuals and/or failed to identify or appropriately control known confounders and/or failed to carry out a sufficiently long and complete follow-up of patients. By poor quality study we mean one that failed to clearly define comparison groups and/or failed to measure exposures and outcomes in the same (preferably blinded), objective way in both cases and controls and/or failed to identify
	Split-sample validation is achieved by collecting all the information in a single tranche, then artificially dividing this into “derivation” and “validation” samples.
††	An “Absolute SpPin” is a diagnostic finding whose specificity is so high that a diagnosis. An “Absolute SnNout” is a diagnostic finding whose N
	benefits.
†††	the ‘reference’) implies a level 4 study.
††††	
	Validating studies test the quality of a specific diagnostic test, based on prior evidence. An exploratory study collects information and trawls the data (e.g. using a regression analysis) to find which factors are ‘significant’.
	emerge (eg 1-6 months acute, 1 - 5 years chronic)

**Grades of Recommendation**

A	
B	or
C	or
D	or

“Extrapolations” are where data is used in a situation which has potentially clinically important differences than the original study situation.

## Appendix 2

### HEALTH TECHNOLOGY ASSESSMENT (HTA) - PROTOCOL ENDOBRONCHIAL ULTRASOUND (EBUS)

#### 1. BACKGROUND INFORMATION

commonest cancer in males (13.8% of cancer in males) and the 8 females (3.8%). The Age-standardized incidence (ASR) was 20.3 for males and 6.5 for females.

of all cancers in males. Similarly, the incidence is lower among females (7.8%).

Conventional radiologic imaging is suboptimal in the detailed delineation of these structures.

needle aspiration (TBNA) – EBUS scope.

For applications inside the central airways, flexible catheters and probe have been developed

can be visualized. The probes can be applied with regular flexible endoscopes that have a biopsy

XBF-UC40P) has been developed that makes needle punctures under real-time endoscopic

needle inserted through the biopsy channel during scanning. Current indications according to the structures. Medical indications are early detection and tumour staging, inflammatory destruction

#### 2. POLICY QUESTION

Should EBUS be made available in Regional Respiratory Centres in Malaysia?

#### 3. OBJECTIVE

lung diseases, specifically in the diagnostic and therapeutic properties

Centres

## 4. SCOPE

The scope of this report is regarding the use of Endobronchial Ultrasound (EBUS), irrespective

### 4.1 INCLUSION CRITERIA

4.1.5 Competing technologies for similar application

### 4.2 EXCLUSION CRITERIA

## 5. ASPECT TO BE CONSIDERED

### 5.1 EFFECTIVENESS

The effectiveness of using EBUS in the management of lung diseases, specifically in the

### 5.2 SAFETY

### 5.3 COST EFFECTIVENESS

### 5.4 ORGANIZATIONAL ASPECTS

- 
- To find out the resources available and needed if this technology is to be introduced particularly the financial resources and man-power.
- Training needed in implementation

## 6. STRATEGY

- Adopt or adapt other HTA
- New HTA

## 7. METHODOLOGY

- Review existing HTA
- Retrieval of evidence
- Analysis of evidence
- HTA writing
- Feedback on draft report and preparation for final report
- Presentation of report to HTA TAC
- Presentation of report to HTA & CPG Council
- Implementation of HTA report

## Appendix 3

## Regional Lymph Node Stations For Lung Cancer Staging (Mountain &amp; Dresler, 1997)

**Superior Mediastinal Nodes**

- 1 Highest Mediastinal
- 2 Upper Paratracheal
- 3 Pre-vascular and Retrotrachea
- 4 Lower Paratracheal (including Azygos Nodes)

N<sub>2</sub> = single digit, ipsilateral

N<sub>3</sub> = single digit, contralateral or supraclavicular

**Aortic Nodes**

- 5 Subaortic (A-P window)
- 6 Para-aortic (ascending aorta or phrenic)

**Inferior Mediastinal Nodes**

- 7 Subcarinal
- 8 Paraesophageal (below carina)
- 9 Pulmonary Ligament

**N<sub>1</sub> Nodes**

- 10 Hilar
- 11 Interlobar
- 12 Lobar
- 13 Segmental
- 14 Subsegmental

Regional lymph node stations for lung cancer staging. Adapted from Naruke et al and the ATS/ North American LCSG2

**Table 1 : Lymph Node Map Definitions (Mountain & Dresler, 1997)**

Nodal Station	
<b>N2 nodes—All N2 nodes lie within the mediastinal pleural envelope</b>	
	Nodes lying above a horizontal line at the upper rim of the brachiocephalic (left innominate)
	Nodes lying above a horizontal line drawn tangential to the upper margin of the aortic arch and below the inferior boundary of No. 1 nodes
	Prevascular and retrotracheal nodes may be designated 3A and 3P; midline nodes are
	and contained within the mediastinal pleural envelope; the lower paratracheal nodes on the
	Researchers may wish to designate the lower paratracheal nodes as No. 4s (superior) and No. 4i (inferior) subsets for study purposes; the No. 4s nodes may be defined by a the azygos vein; the No. 4i nodes may be defined by the lower boundary of No. 4s and the lower boundary of No. 4, as described above
5. Subaortic (aorto-pulmonary window)	artery and proximal to the first branch of the left pulmonary artery and lie within the
6. Para-aortic nodes (ascending aorta or phrenic)	Nodes lying anterior and lateral to the ascending aorta and the aortic arch or the innominate
	Nodes lying caudal to the carina of the trachea, but not associated with the lower lobe
8. Paraesophageal nodes (below carina)	Nodes lying adjacent to the wall of the esophagus and to the right or left of the midline,
	Nodes lying within the pulmonary ligament, including those in the posterior wall and lower
<b>N1 nodes - All N1 nodes lie distal to the mediastinal pleural reflection and within the visceral pleura</b>	
	The proximal lobar nodes, distal to the mediastinal pleural reflection and the nodes adjacent to the bronchus intermedius on the right; radiographically, the hilar shadow may be created
	Nodes lying between the lobar bronchi
	Nodes adjacent to the distal lobar bronchi
	Nodes adjacent to the segmental bronchi
	Nodes around the subsegmental bronchi

**Evidence table**      **EFFECTIVENESS OF EBUS IN LUNG TUMOUR**  
**Question**            **Is EBUS effective when used in the analysis/ diagnosis of Central Cancer?**

**NO. 1**
